POPULATION IN FARM-OPERATOR HOUSEHOLDS

Helen R. White, Division of Farm Population and Rural Life, Bureau of Agricultural Economics

INTRODUCTION

The number and characteristics of persons in farm-operator households have both simple and complex relations with the number of farms and their characteristics. The apparent simplicity of some of the relationships can be illustrated in a cursory examination of the geographic distribution of farms and the population in farm-operator households. The relative distributions in 1950 were as follows:

Region	Farms	Population in farm-operator households
United States.....	100	100
North.....	42	40
South.....	49	52
West.....	9	8

Obviously, the number of persons in the farm-operator household population is determined rather largely by the number of farms. The difference between the two percentages for a given region are directly attributable to variations in the average size of household among the regions and indirectly to the numerous factors affecting the average size of household. (In the United States, residence of the operator and other members of his household in a geographic area other than that in which his farm is located is a very minor factor in the differences between the relative geographic distributions of farms and of farm-operator household population. Less than 39,000 of the more than 5 million farms covered by the 1950 Census of Agriculture were not located in the enumeration district in which the farm operator resided. As agriculture and population schedules were matched only when the operator's residence and farm were in the same enumeration district, technically these data do not reflect this minor source of variation. In view of the small numbers involved, this factor can be ignored as a source of variation among regions.)

The complexity of the relations between the number and characteristics of the farm-operator household population and the number and characteristics of the farms can be illustrated in an examination of variations in the size of households by economic class of farm. The larger the size of the farm-operator household, the greater the potential manpower available for operating the farm and the greater the possibilities of economic achievement. But this is true, of course, only within the limits set by age, education, sex, health, and other characteristics of the people in the household and the quality of the soil, equipment and capital available, size, and other characteristics of the farm. On the other hand, having more persons economically dependent on a farm than the farm can support may lead to depletion of the physical resources and underutilization of the human resources of the farm. The relative economic success of the farming operations also affects the size of the household. If the net profit from the farming operations is small, members of relatively large families may have additional motivation to seek employment off the family farm; this frequently involves migration from the family residence and a consequent reduction in the size of the household. Conversely, children of successful farmers are more likely to be well-educated and, therefore, to seek employment in other fields and other areas.

These relationships are shown by the data for this report. In the North and West (combined), the average size of household decreased consistently from 4.2 persons per household for economic classes I and II to 2.9 for class VI. In the South, where families are generally larger, the average size of household increased from 3.9 for classes I and II to 4.7 for class IV and then decreased to 4.1 for class VI. The average size of the households on part-time farms (including abnormal) and of residential farms was larger in both the North and West and in the South than those of class VI farms. Substantial proportions of the operators of part-time and residential farms worked off the farm 200 days or more. In fact, the income from other sources exceeded the value of the farm products sold for approximately 87 percent of the

families of part-time farm operators and for approximately 65 percent of the families of residential farm operators but for none of the families of class VI farm operators. (The definition of class VI farms excludes from this group families whose other income exceeds farm sales.) Thus, the class VI families are economically less able to retain members of their households than the part-time or residential families.

The variation in the size of households is reflected in the relative distributions of farms and of farm-operator household population by economic class of farm (table 1). The proportion of farms in classes I through IV was 50 percent, 22 percent, and 52 percent in the North, South, and West, respectively, in 1950. The corresponding proportions of the farm-operator household population in these classes was 61 percent, 23 percent, and 55 percent.

Residential.....	3,915,625	932,182	2,700,644	282,799
PERCENT DISTRIBUTION				
All farms.....	100.0	100.0	100.0	100.0
Commercial farms.....	70.4	79.4	63.3	72.0
Classes I and II.....	9.1	14.7	3.0	21.3
Class III.....	14.1	24.0	6.0	17.8
Class IV.....	17.3	21.9	14.1	15.8
Class V.....	17.3	13.5	20.9	12.3
Class VI.....	12.6	5.4	19.3	4.8
Other farms.....	29.6	20.6	36.7	28.0
Part-time and abnormal.....	11.7	9.9	13.1	11.7
Residential.....	17.9	10.7	23.7	16.3

In the North and West more than half of the farm-operator household population was in households of operators of classes I through IV farms—farms for which the total value of products sold was equal to or exceeded \$2,500. In the South, which contained approximately half of the total farm-operator household population, less than a fourth of the farm-operator household population was associated with farms of classes I through IV. Of the roughly 13 million persons in the United States in households of operators of farms classified as classes V, VI, part-time, residential, and abnormal, 60 percent were in the South.

DEFINITION OF FARM POPULATION AND POPULATION IN FARM-OPERATOR HOUSEHOLDS

Problems in defining farm population.—In the United States, the term "farm population" is popularly associated with the idea of farm-operator families which live on the farms they operate and which depend entirely or largely on farming for their livelihood. This concept has arisen from our historic way of living and farming. Even today approximately 95 percent of the farm operators live on the farm they operate and roughly 66 percent receive more gross income from the farm than from other sources. Superficially it would seem that a completely satisfactory classification of population into farm and nonfarm could be constructed on the basis of farm residence. However, in many other parts of the world and even in some parts of the United States the typical farm-family settlement pattern is a village or cluster of homes not on, but surrounded by, farmland. For

example, in 1950, roughly 19 percent of the farm operators in Utah did not live on farms.

There are other difficulties in the practical application of the above concept to the problem of classifying population as farm or nonfarm. An increasing proportion of farm operators are doing work other than on their own farm. If the farm operator does not do any work other than on his own farm, other members of his family may have off-farm work. In addition to problems relating to the residence and degree of dependence on agriculture of farm-operator families, there are problems in classifying other groups. These include such groups as farm laborers or farm-laborer families residing on farms, farm-laborer families not residing on farms, and families or single individuals renting farm houses but not renting any of the farmland in the property. If the classification is based on farm residence, a practical and valid way of identifying farms must be established. Because of these and other problems, censuses conducted by other countries have tended to include tabulations of the population dependent on agriculture based on the occupation or industry classification of persons in the labor force; persons not in the labor force being allocated to the occupation or industry group of the head of their household or of the person on whom they are economically dependent. (Problems in classifying the population dependent on agriculture are discussed in greater detail in a report prepared by the United Nations entitled *Population Census Methods*, Lake Success, New York, 1949, pp. 145-158. Some specific aspects of the problem in the United States are described in the joint Bureau of the Census and Bureau of Agricultural Economics report entitled *Farm Population*, Series Census-BAE, No. 16, March 1953.)

Definition of farm population.—In the 1950 United States Census of Population and Housing, the residence classification of population into farm and nonfarm was made largely on the basis of responses to the question "Is this house on a farm (or ranch)?" However, enumerators were instructed to classify as nonfarm all persons in institutions, summer camps, tourist cabins, and similar places on farms and all persons paying cash rent for a farm house and yard but not renting any of the farmland. Both the farm and nonfarm populations have been further classified according to urban and rural residence. (Relatively little data are available on the characteristics of the urban-farm or total farm population, the three-way classification of urban, rural non-farm, and rural farm having been used most frequently.)

Definition of population in farm-operator households.—The definition of the population in farm-operator households is fairly obvious from examination of the basic definitions of a farm, a farm operator, and a household given in the Introduction to this report.

However, the following facts need to be remembered in evaluating and analyzing the data in this report:

1. The population data in this report relate only to the farm-operator households for places counted as farms in the 1950 Census of Agriculture.
2. Data on farm-operator households for approximately 39,000 or 0.8 percent of all farm operators were not tabulated as the farm operators lived in enumeration districts other than the enumeration district in which the farm was located.
3. Some households located on farms and containing persons counted as farm population in the 1950 Census of Population do not contain a farm operator, and are, therefore, not included in the data given in this report. Such households include households of farm laborers and farm landlords not operating farms but living on farms, as well as households on places considered as farms but without sufficient agricultural operations and agricultural production to qualify as farms according to the definition used for the 1950 Census of Agriculture.
4. The population data in this report include persons in a considerable number of households containing a farm operator who were not counted as part of the farm population in the 1950 Census of Population because the household was not considered as being on a farm.

The following data indicate the relative composition of the farm population for the 1950 Census of Population and the population in farm-operator households as estimated from tabulations made for this report:

Item	Farm population, 1950 Census of Population 123,332,000	Farm-operator household population 21,875,000
Total population.....		
Persons included in farm population and in farm-operator household population.....	20,851,000	20,851,000
Persons included in farm-operator household population but not as farm population in Census of Population.....	xxxxxxxxxx	1,024,000
Persons included in farm population but excluded from farm-operator household population because place did not qualify as farm ²	1,756,000	xxxxxxxxxx
Other persons not included in farm-operator households, but included in farm population ³	725,000	xxxxxxxxxx

¹Total farm population as shown by the 1950 Census of Population.

²Estimates based upon tabulation of data for a sample of 1,408 households taken from 5,260 or 5 percent of the enumeration districts having farms in 1950. This figure is subject to considerable sampling variability.

³Estimates obtained by subtracting totals for groups listed from the total farm population.

The above data indicate that the population of farm-operator households included in this report and included in the farm population as shown for the 1950 Census of Population represented 20,851,000 persons or 89 percent of the 23,332,000 farm population. On the other hand, the population of farm-operator households includes 1,024,000 persons not included in the 1950 farm population. Also, the 1950 farm population included 2,481,000 other persons not included in the population of farm-operator households. This total comprises 1,756,000 persons in households on places considered as farms in the 1950 Census of Population, but not qualifying as farms for the Census of Agriculture and 725,000 persons in other households not containing a farm operator. These households consist largely of households of farm landlords and farm laborers.

The relationship of the population of farm-operator households to total farm population should be considered in using data in this report to supplement data on farm population.

AGE, SEX, AND COLOR COMPOSITION OF THE POPULATION IN FARM-OPERATOR HOUSEHOLDS

Age.—As approximately 21 million of the 23 million persons in the total farm population of the United States in April 1950 were also part of the 22 million persons in farm-operator households, the similarity of the age-sex distribution of the farm-operator household population to that of the rural-farm population shown in diagram 1, is not surprising. (Differences between these two groups are attributable to exclusion of persons in urban farm-operator households from the rural-farm population as well as to the points previously discussed.) The population pyramids for both of these groups have much broader bases, representing larger proportions of persons under 20 years of age, than the urban population. The slimmness of these columns from ages 20 to 24 years through 40 to 44 years and more rectangular shape from 20 to 24 years through age 59 also contrasts with the breadth in the young adult ages and more tapering shape of the urban pyramid.

Even though the number of young persons in the farm-operator household population is relatively large, it does not seem excessive in terms of long-run replacement needs assuming that each of the present operators will eventually be replaced by another. In April 1950, there were roughly 107 males under 35 years of age (excluding operators) for every 100 operators. (This figure is an understatement insofar as it does not allow for females of any age or older males who are not operators or for persons not in farm-operator households who may become operators.) Some of these young males will prefer nonfarm employment; some will, of course, die prior to the death or retirement of the present operators. If the number of farms continues to decline—there was a decrease of about one-fifth between 1935 and 1950—the number of operator-

Diagram I.-SELECTED POPULATION GROUPS BY AGE AND SEX FOR THE UNITED STATES: 1950

replacements needed will also decline. As approximately 168 males in the farm-operator household population will reach age 20 during the next decade for every 100 expected deaths or retirements among males 20 to 64 years of age, absorption of almost all of these males into the farm labor force is not expected. (The figure 168 is specifically the ratio, multiplied by 100, of expected survivors to 1960 of males 10 to 19 years of age in 1950 to the sum of (1) expected deaths during 1950-60 to males 20 to 54 years of age and of (2) males 55 to 64 years of age in 1950, assuming the 1950 level of mortality.) This figure is lower than the similar replacement rate for rural-farm males for 1940-50, the value of which was 179 (Conrad Taeuber, *Replacement Rates for Rural-Farm Males Aged 25-69 Years, by Counties, 1940-50*, Bureau of Agricultural Economics, U. S. Department of Agriculture, 1944).

The relatively large number of young people and of aged persons in the rural-farm population and in the farm-operator household population represent an added burden of dependency on the economically active members of these groups. Crude measures of this dependency load, the ratio of persons under 15 years and 70 years and over to persons 20 to 64 years of age, for 1950, are as follows:

Residence	Ratio
United States.....	54.7
Urban.....	46.6
Rural nonfarm.....	64.4
Rural farm.....	75.1
Farm-operator household population.....	72.5

Persons 15 to 19 years of age and 65 to 69 years of age are deliberately omitted from both the numerator and denominator of this ratio because significant numbers of these groups are in the labor force and because of urban-rural differentials in employment opportunities for persons in these age groups. Not only do the rural-farm and farm-operator household populations have greater dependency loads, but the income available for support of these dependents is less than that available to the urban and rural-nonfarm populations. (Figures on family income for the various residence groups do not indicate fully differences in family income per capita because of differences in family size and because they do not take into account the value of home-produced farm products consumed by rural families.) The median income in 1949 of families and unrelated individuals in these population groups was as follows:

Residence	Median income (dollars)
United States.....	2,619
Urban.....	2,970
Rural nonfarm.....	2,186
Rural farm.....	1,567
Farm-operator household population.....	1,867

(See chapter 3 for analysis of income variations and for discussion of the limitations of these data. The number of unrelated individuals in the farm-operator household population was relatively small.)

Variations in the age-sex composition of the population in farm-operator households by economic class of farm are shown in diagram 2. The most obvious contrast is the more pyramidal distribution of the population associated with classes I and II farms and class III farms and the gradual shift to the more rectangular distributions of groups under 20 years and 20 years of age and over in classes V, VI, and residential. In fact, the distribution of the population associated with classes I and II farms resembles that of the urban population except for the relatively greater numbers of persons 5 to 19 years of age on the high-income farms.

The increase in the proportion of aged persons from classes I and II to class VI is striking. While only 4.7 percent of the population associated with classes I and II was 65 years old or older, 11.5 percent of the population associated with class VI farms was in this age group. The corresponding percentages for the population on part-time and residential farms were 6.7 and 9.4, respectively. Detailed percentage distributions for each economic class are given in table 2.

The proportion of persons under 15 years of age tended to increase from classes I and II to V, rising from 31.1 percent to 33.3 percent. In the population associated with class VI farms, however, only 30.9 percent were under 15 years of age. Thus, despite the increase in the proportion of aged persons from classes I and II to class VI, the median age decreased from 27.6 years for classes I and II to 26.0 for class V (table 3). For the population on class VI farms, however, the median age was 28.6 years.

TABLE 3.—MEDIAN AGE OF THE POPULATION IN FARM-OPERATOR HOUSEHOLDS, BY SEX AND BY ECONOMIC CLASS OF FARM, FOR THE UNITED STATES AND REGIONS: 1950

[Data are based upon a sample. For a description of the sample and a statement of reliability of the data, see page 3. For limitations of the data, see text, page 63]

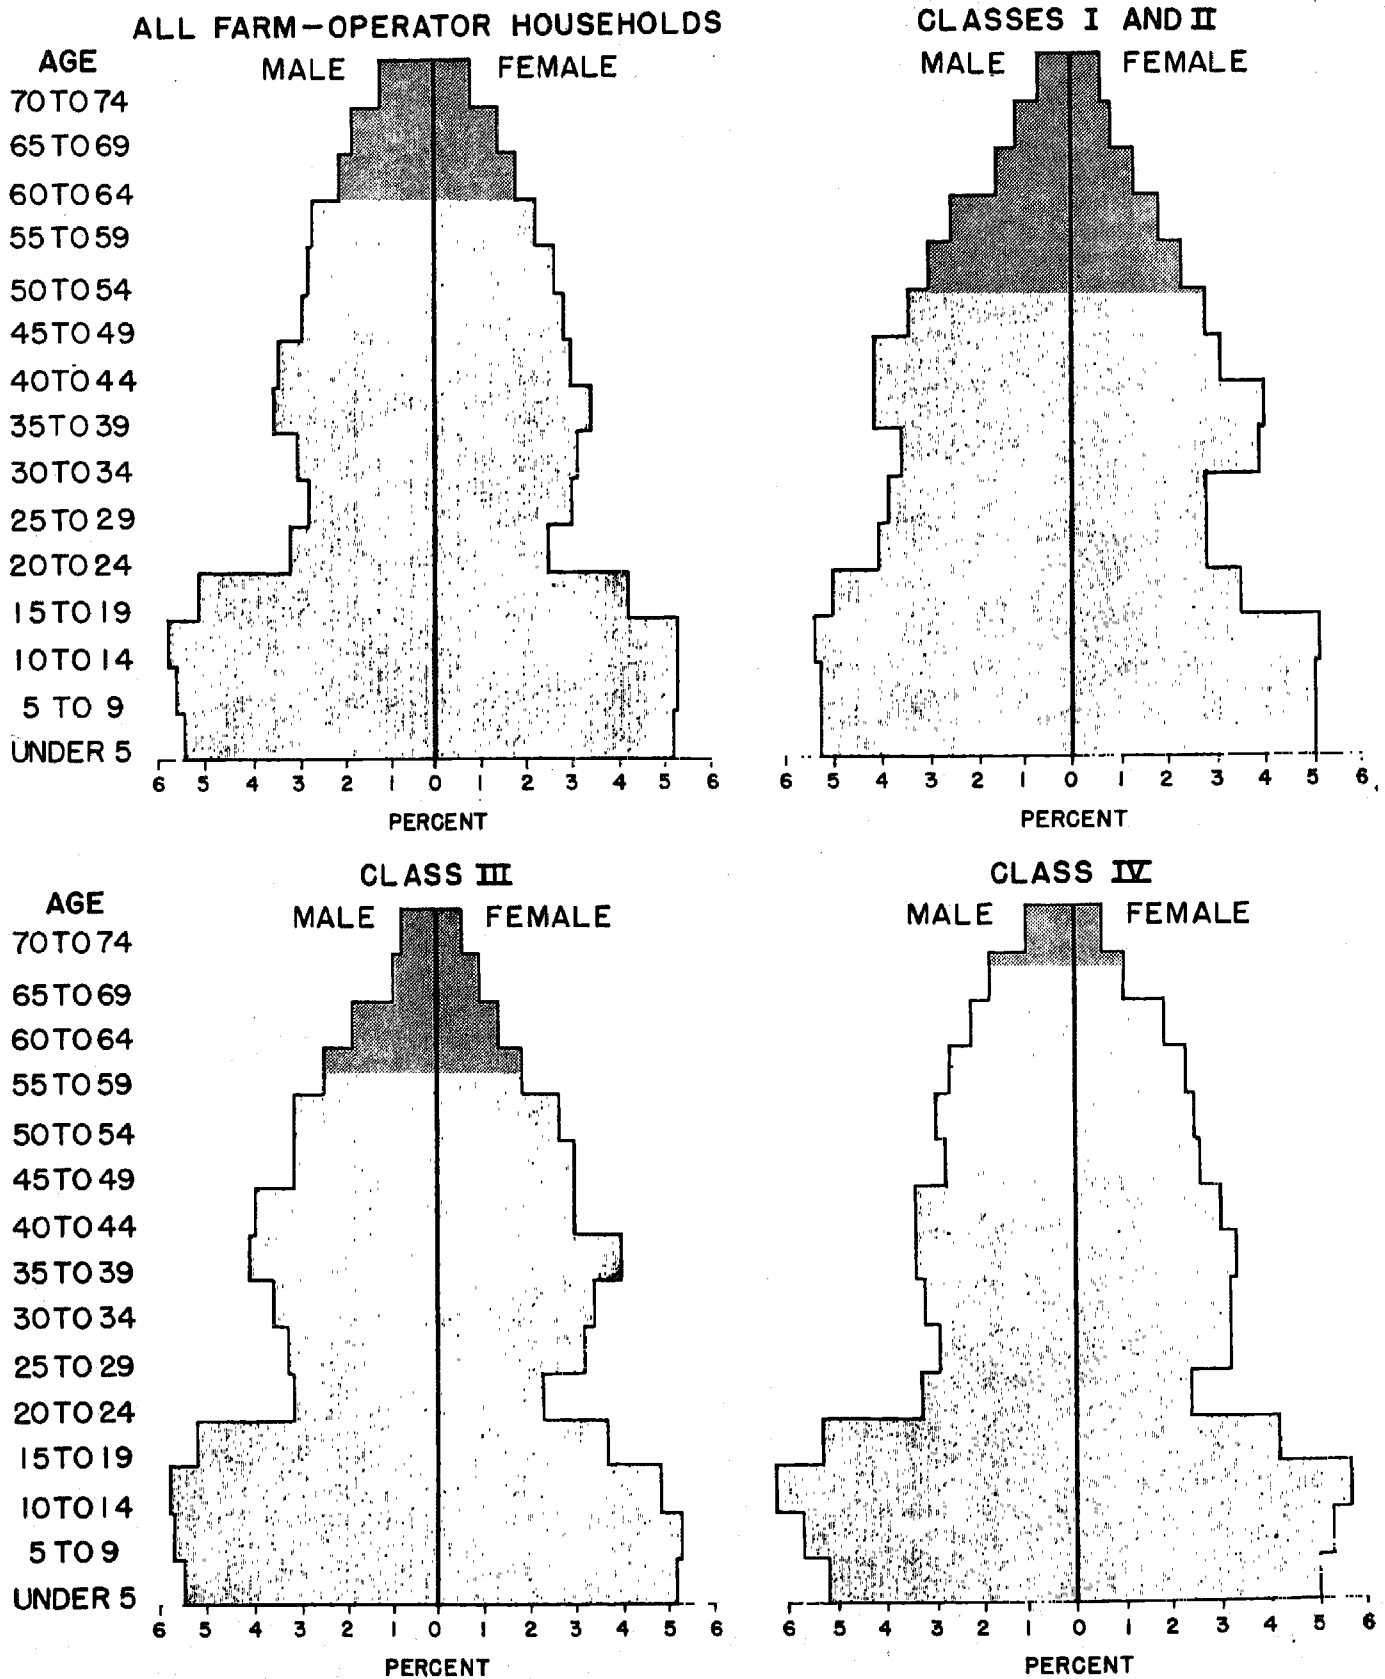

Economic class of farm	United States			North and West			South

Class V.....	26.0	25.7	26.3	33.2	33.4	33.0	22.0	21.8	22.2
Class VI.....	28.6	29.3	28.0	46.2	47.5	44.5	25.0	25.4	24.7
Other farms... Part-time and abnormal..... Residential.....	26.9	26.4	27.3	29.6	30.2	29.2	25.5	24.6	26.3
	27.0	26.8	27.2	29.7	30.2	29.2	25.5	25.1	25.8
	26.8	26.0	27.4	29.6	30.1	29.2	25.4	24.3	26.6

The age structure of the population associated with each economic class of farm reflects to some extent the age distribution of farm operators. As shown in table 4, the age distributions of operators change from a peaked, clustered form for classes I and II to a more flattened, dispersed form for class VI. Classes V and VI contained both greater proportions of young operators and greater proportions of old operators. The age distributions of the operators of both class VI and operators of residential farms are more markedly skewed toward the older ages. The statement that the age structure of the population in each economic class reflects the age distribution of the operators may seem slightly strange at first glance. The median age of all persons in class V farm-operator households was 1.6 years lower than the median age of all persons in classes I and II farm-operator households; the median age of other members of class V households was only 1 year less than that of classes I and II; but the median age of class V operators was 3.9 years higher than the median age of classes I and II operators. Thus, there is a smaller decrease (or an actual increase) between classes I and II and class V for the two components than for the whole. Four factors contribute to this apparent anomaly: (1) A median simply divides a distribution into two groups of equal size without regard to the distribution of items within these two groups; (2) a larger proportion of class V operators than of classes I and II operators were under 25 years of age; (3) a larger proportion of non-operator members of class V households than of classes I and II households were in the younger age groups; and (4) non-operators are greater in number than operators in both groups.

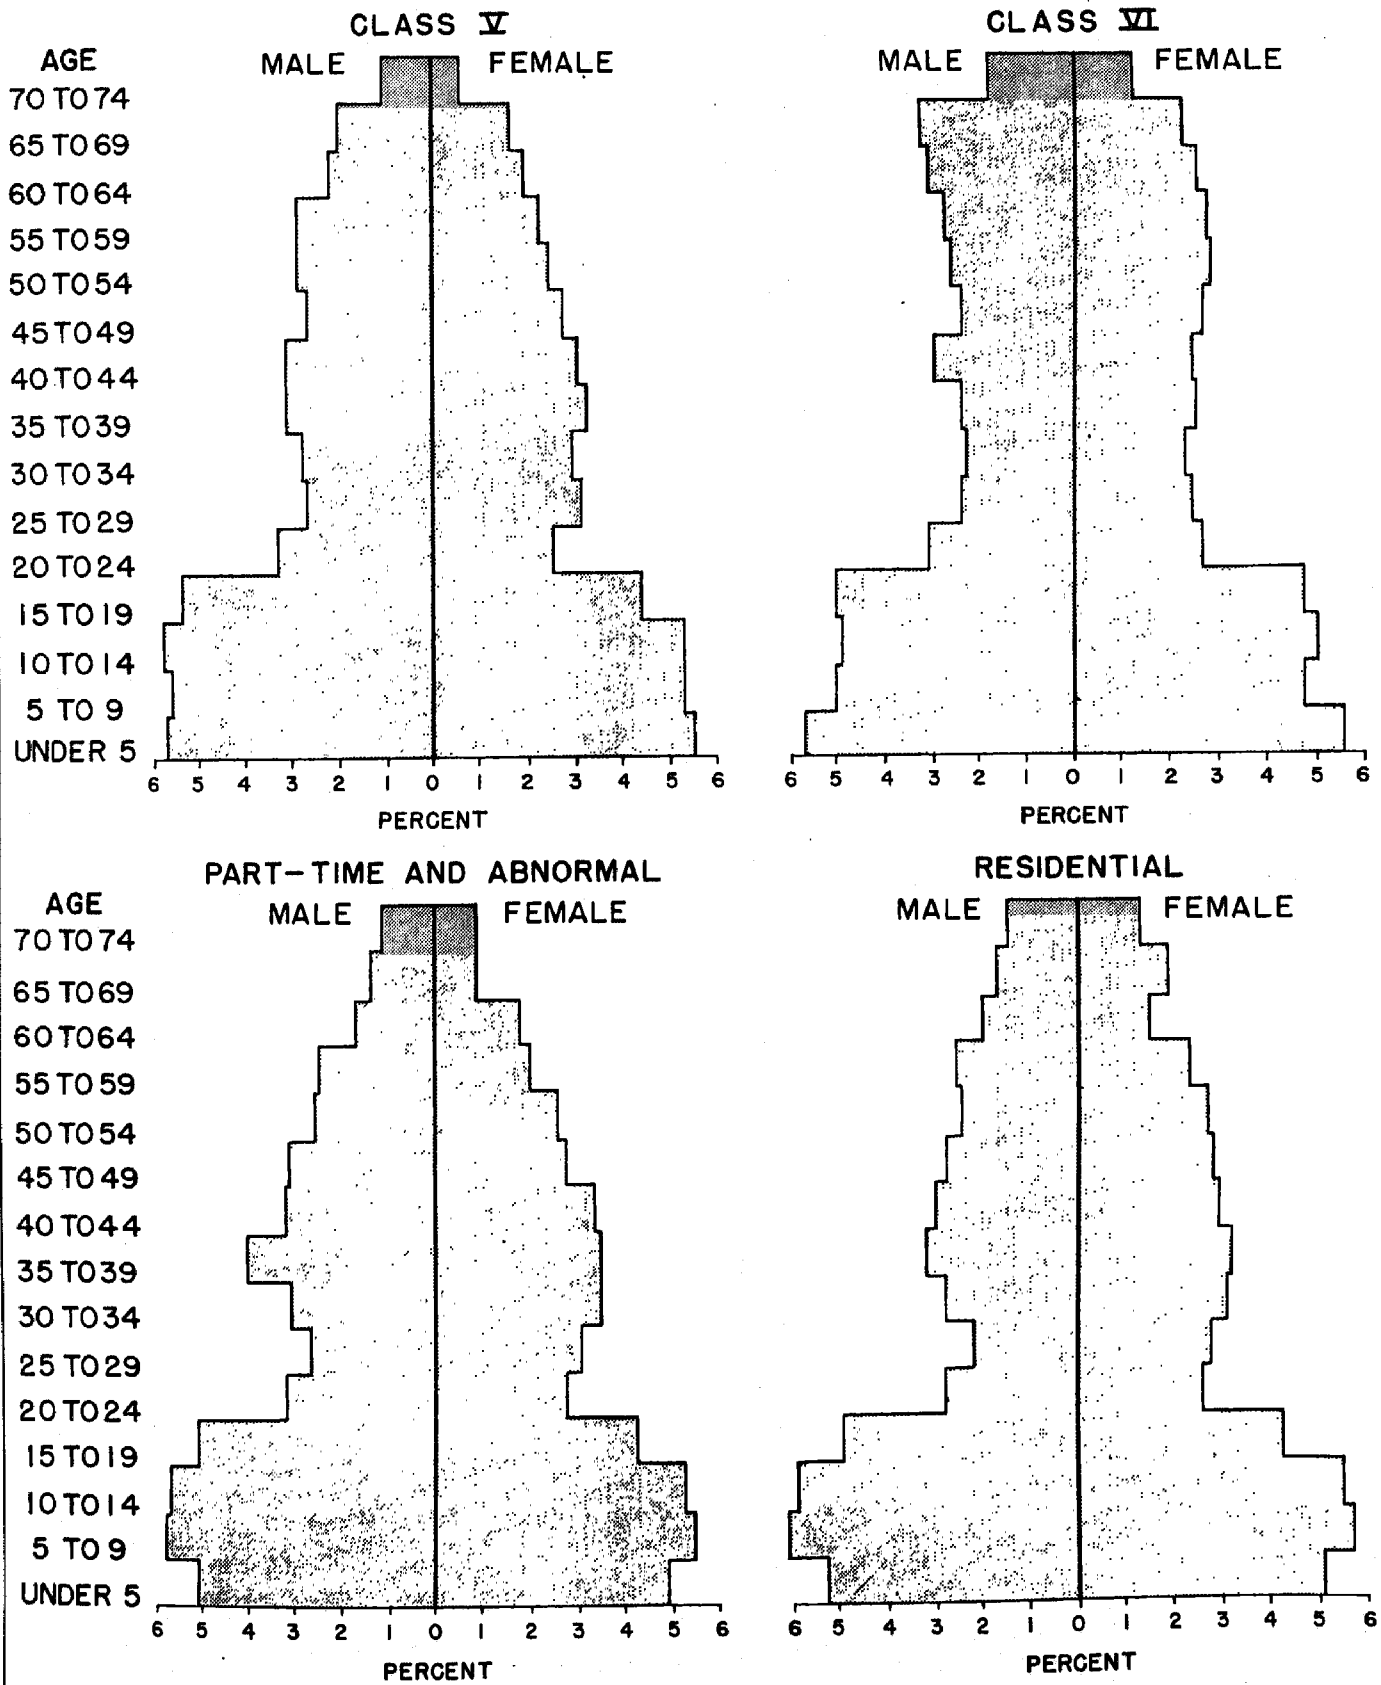

Both the age of the operator and the age of the other members of the household affect the productivity of the farm and consequently its economic class. Older operators, particularly those 65 years of age and over, lack the physical strength of healthy young adults; they may be semiretired; and some or all of their children may have left the household. Thus, those operators 25 to 54 are likely to be more productive, to have more productive farms, and a greater value of farm products sold. In fact, roughly 11 percent of the operators 25 to 54 years of age had classes I and II farms as contrasted with 6 percent of the operators under 25 or 55 years of age and over.

Insofar as gross value of products sold is an indicator of the income available to the household, those farm-operator households least able to support a large number of dependents have the largest ratios of persons in the dependent ages to persons in the working ages. As shown in table 5, the number of persons in the

¹Includes only farm operators for which population data are available.²Computed from detailed age distribution.

dependent ages per 100 persons in the working ages, increases from classes I and II to class VI. Although the increase in the number of persons under 15 years of age per 100 persons 20 to 64 years of age is sizable, the increase in the number 70 years and over per 100 persons 20 to 64 years of age is even more marked. The latter ratio rises from 4.9 for classes I and II to 12.6 for class VI.

Because of higher fertility, higher mortality, and greater net losses through migration after childhood, the farm-operator household population in the South is younger than that in the North and West. From the data tabulated for this report, the median age was estimated to be 24.1 years in the South and 29.9 years in the North and West in April 1950. For each of the economic classes except I and II, the median ages were also lower in

the South. These differences between the median ages in the South and in the North and West increase from 2.9 years for class III to 21.2 years for class VI. Southern farm operators were also somewhat younger than those in the North and West, although the regional differences are by no means as marked for these groups as for all household members. The regional differences in median age of farm operators were greatest for classes V and VI (see table 3 of chapter 5).

Higher fertility, higher mortality, and greater net losses through migration in the South also account for the higher dependency ratios found in this region. The greater number of persons in the dependent ages (under 15 and 70 years and over) per 100 persons in the working ages (20 to 64 years) in the South

relative to the North and West is due entirely to the relatively greater proportions of persons under 15 years per 100 persons in the working ages. In every economic class except part-time and residential, the number of persons 70 and over per 100 persons in the working ages was lower in the South than in the North and West. With respect to dependency ratios as well as median age, differences between the South and the North and West were least for classes I and II. As these classes are the more cosmopolitan part of the farm-operator household population, the similarity of the South to the North and West is not unexpected. (Data for classes I and II for the South in this report must be used with caution as they are based on a relatively small number of farms.)

Sex.—Diagram 1 shows that in April 1950 the rural-farm population and the population in farm-operator households contained somewhat larger proportions of males than females. More precise measures of the sex composition of these populations can

be made in terms of the number of males per 100 females. The data for April 1950 are as follows:

Residence	Number of males per 100 females	
	All ages	14 years of age and over
United States.....	98.6	97.0
Urban.....	94.6	92.2
Rural nonfarm.....	103.6	103.2
Rural farm.....	110.1	112.2
Farm-operator household population.....	(1)	112.1

(1) Not available. See section of this chapter on "Limitations of Data."

These particular values of the number of males per 100 females—the sex ratio—have been brought about by a number of factors.

FARMS AND FARM PEOPLE

In the United States the sex ratio of births has had a fairly constant value of about 106. Births, therefore, tend to cause the sex ratio of the total population to approach 106. The higher the birth rate, the greater the effect of births on the sex ratio of the total population. The sex ratio for the population of the United States would, of course, be the same for all age groups if it were not affected by differential mortality and international migration. During the past decade, withdrawal of men from continental United States to the armed forces overseas has also been an important factor. The rather large differences in the sex ratios of the various residence groups within the United States in 1950 represent primarily the effects of internal migration.

Variations in the sex ratio by age within the farm-operator household population resembled those of rural-farm population, as shown below.

Age	Rural farm	Farm-operator household population
14 years and over.....	112.2	112.1
14 to 24 years.....	116.7	122.4

35 to 44 years.....	105.3	106.8
45 to 54 years.....	110.0	107.6
55 to 64 years.....	121.8	120.4
65 years and over.....	128.5	127.0

As there were 116.7 males for every 100 females in the rural-farm population 15 to 24 years of age in 1940—those who would be 25 to 34 years old in 1950—the low sex ratio of the 25-to-34 year old group reflects largely the influences of World War II.

Although the age distribution of population associated with classes I and II farms was similar to the urban population, the sex composition was not. In fact, the sex ratio was, with one exception, higher for classes I and II in every age group shown in table 7 than for any other economic class. Males on high-income farms have less economic motivation toward migration than those on low-income farms. Conversely, a farm with few adult males to share the farm work may be less productive and, therefore, in a lower economic class than it would otherwise be. The decrease in the sex ratio from classes I and II to class VI is shown in table 7. Even more pertinent than the decrease in the sex ratio is the decrease in the average number of working-age males. As shown below, classes I and II farms averaged somewhat more than one working-age male in the household while class VI farms averaged less than one.

Economic class	Males 20 to 64 years old per farm
All farms.....	1.08
Commercial farms.....	1.11
Classes I and II.....	1.28
Class III.....	1.19
Class IV.....	1.13
Class V.....	1.06
Class VI.....	0.92
Other farms.....	1.02
Part-time and abnormal.....	1.08
Residential.....	0.98

FARMS AND FARM PEOPLE

Color of population.—Roughly one-seventh of the total population in farm-operator households in April 1950 were nonwhite. As shown below, nonwhites formed larger proportions of the rural-farm and farm-operator household populations than of the urban or rural-nonfarm populations:

Residence	Percent nonwhite
United States.....	10.5
Urban.....	10.1
Rural nonfarm.....	8.7
Rural farm.....	14.5
Farm-operator household population.....	13.7

Although the proportion of nonwhites in the total population has been relatively constant during the last 30 years, there have been significant changes in the proportions which they form of the three major residence groups and in their distribution by residence. The residence distribution of nonwhites from the Population Censuses of 1930, 1940, and 1950 was as follows:

Residence	1950		1940	1930
	New urban definition	Old urban definition		
United States.....	100.0	100.0	100.0	100.0
Urban.....	61.6	58.8	47.9	43.2
Rural nonfarm.....	17.2	20.1	16.7	17.3
Rural farm.....	21.2	21.2	35.3	39.5

Thus, the relatively high fertility of the nonwhite rural-farm and farm-operator household population has been more than offset by losses through net migration from the farm population and by mortality. (Eleanor H. Bernert has estimated that between 1930 and 1940, net migration rates for nonwhite rural-farm males and females were -17.1 and -22.4 percent, respectively. Corresponding rates for white rural-farm males and females were -9.0 and -14.0 percent, respectively. See *Volume and Composition of Net Migration from the Rural-Farm Population, 1930-40, for the United States, Major Geographic Divisions, and States*, United States Department of Agriculture, Bureau of Agricultural Economics, 1944.)

As a result of higher fertility, mortality, and net loss through migration among the nonwhite farm-operator household population, the median age was much lower than that of the corresponding white population or that of the urban nonwhite population. In April 1950, the median ages of the various white and nonwhite residence groups were as follows:

Residence	White	Nonwhite
United States.....	30.8	26.1
Urban.....	32.0	28.7
Rural nonfarm.....	28.4	23.5
Rural farm.....	27.9	18.5
Farm-operator household population.....	28.6	18.8

Detailed age distributions of the white and nonwhite farm-operator household populations are shown in tables 9 and 10.

A study of the relative mobility of the populations associated with the different economic classes of farms and different income classes would aid considerably in the analysis of the relative age distributions of the white and nonwhite farm-operator household population. As the median ages of the total white population and of the total nonwhite population of the United States differ by less than 5 years, the greater disparity in the median ages of the white and nonwhite farm-operator household populations may be largely associated with disparities in income. More than half of the nonwhite farm-operator household population was in classes V and VI as contrasted with about one-fourth of the white farm-operator household population (table 8). Probably within any one of the economic classes, larger proportions of nonwhites than of whites have lower incomes.

OTHER POPULATION CHARACTERISTICS

Marital status of farm operators.—In April 1950, almost 90 percent of the farm operators were married (table 12) as con-

TABLE 10.—POPULATION IN FARM-OPERATOR HOUSEHOLDS, BY AGE AND COLOR, FOR THE UNITED STATES AND THE SOUTH: 1950

trasted with only 64 percent of rural-farm males 14 years of age and over. (Data on marital status by age groups from the 1950 Population Census are not available.) The higher proportion married among farm operators reflects primarily their older age distribution and better economic position. Inclusion of some non-farm persons, of some urban persons (both farm and nonfarm), and of some women in the operator group is probably of minor importance. The older age distribution is probably the most important factor, for if rural-farm males had had the same age distribution as farm operators, roughly 80 percent rather than 64 percent would have been married. In the distribution by economic class of farm, the high proportion of widowed and divorced among the operators of classes V and VI, part-time, and residential farms is of interest. This high proportion is attributable largely to the older age distribution of these groups of operators.

¹Data are not available on marital status of 39,000 farm operators. These are primarily operators who do not reside in the enumeration district in which their farm is located.

Years of school completed by farm operators.—The education of the farm operator is undoubtedly associated with the quality of the farm and equipment which he inherits or is initially able to buy, and with the efficiency with which the farm is operated. One or more years of college had been completed by 14 percent of

the operators of classes I and II farms as contrasted with 1 percent of the operators of class VI farms (table 13). The median years of school completed, shown in table 14, dropped from 10.2 years for classes I and II to 6.9 years for class VI. More than three-fourths of the latter group had not completed any years of school above the elementary grades. In view of the age distribution of operators—roughly one-half of whom are more than 47.6 years of age—relatively few of them can be expected to complete any additional years of education.

The median years of school completed by farm operators was the same as that for rural-farm males for April 1950.

Labor-force status and occupation.—Approximately 54 percent of the population 14 years of age and over in farm-operator families were in the labor force in April 1950. Corresponding percentages for the urban, rural-nonfarm, and rural-farm populations were 55, 49, and 51, respectively. About 1 percent of the difference between the percentage for farm-operator families and that for the rural-farm population is probably due to the inclusion of unpaid family workers who worked less than 15 hours as members of the labor force in the farm-operator family data; also the effect of limiting these data to families is difficult to estimate. Some of the difference between the proportion for farm-operator families and for rural-farm population may be real, however, as there are more opportunities for part-time employment of women and older children and for employment of aged and handicapped persons on a farm than in nonfarm work. Probably because of the increase in the proportions of women and of aged males in the populations from classes I and II to class VI, the proportion in the labor force decreased from classes I and II to class VI. (See table 15.)

About 4 out of every 5 persons classified as farm operators in the 1950 Census of Agriculture were reported as farmers or farm managers in the 1950 Population Census. (This proportion and the following percentages relate to operators for whom an occupation was reported.) The proportion of operators who were

reported as farmers and farm managers decreased from 94 percent for operators of classes I to III farms to 86 percent for operators of class V farms (table 16). The higher proportion of class VI than of class V operators reported as farmers and farm managers is due to the definition of class VI and part-time farms; both have a gross value of farm sales of \$250 to \$1,199 but the operators of part-time farms either (1) worked off their farms 100 days or more in 1949 or (2) had nonfarm family incomes which exceeded the values of farm products sold. When class VI and part-time operators are combined, the proportion reported as farmers and farm managers is 71 percent. Thus, the proportions form a more uniform series from classes I and II through residential than is at first apparent.

There are a number of reasons why persons classified as farm operators in the Census of Agriculture were not reported as farmers or farm managers in the Census of Population. As noted on page 6, in the Population Census the occupation classification relates to the job held during the census week, (the calendar week preceding the enumerator's visit) or to the last job held. If an employed person had two or more jobs, the occupation reported is the one in which the greatest number of hours was worked during the census week. In the Census of Agriculture a farm operator is a person who operates a farm, either performing the labor himself or directly supervising it. The classification is not affected by the amount or types of work done during the census week. (These definitions were designed to meet specific needs. Differences between the two types of data attributable to differences

in definition should not be interpreted as casting doubt on the validity or reliability of either.) As approximately 38 percent of the operators had done some off-farm work during the past year, the fact that the farm operator had another job at which more time was spent during the census week probably accounts for most of the operators who were reported in other occupations.

Fertility.—In April 1950, there were 556 children under 5 years old for each 1,000 women 15 to 49 years old in the households of operators of class VI farms. In the households of classes I and II farm operators, there were 450 children under 5 for each 1,000 women 15 to 49 years old. As shown in diagram 3 and in table 18, these ratios (unstandardized) do not increase in an orderly way from classes I and II to class VI. Some of the departure from a fairly smooth progression is caused by variations in the age and marital status of the women associated with different economic classes of farms. (The standardized ratios show what the ratios of each economic class would have been if (1) the age distribution of women for that economic class had been the same as for women in all farm-operator households and if (2) the age and marital status distribution within age groups had been the same as for women in all farm-operator households.) When the effects of these variations are excluded, the resulting ratios standardized for age and marital status increase consistently from classes I and II to class VI.

The failure of part-time and residential farms to fit into this pattern is of particular interest. Even when part-time and class VI data are combined, the ratios do not have an orderly pattern of increase and decrease from classes I and II through residential. (The ratios for the combined group are 489 and 494 unstandardized and standardized for age and marital status, respectively.) Fertility ratios are rather sensitive indicators of heterogeneity between groups. These data are evidence that, even though class VI and part-time farms have the same gross values of farm sales and, with residential, are part of a continuous scale by value of farm sales, part-time and residential are actually special groups which must be treated separately in the economic class of farm scale. (The data on percentage of operators reported as farmers or farm managers are, by their nature, a special case which should not be interpreted as contradicting this conclusion.)

Although the tremendous rise in the number of births and in the birth rate during the 1940's was most marked in the urban

population and has tended to reduce urban-rural differentials in fertility, the number of children under 5 per 1,000 women 15 to 49 was still greater for the rural-farm population than for either the rural-nonfarm or urban populations in 1950. (These ratios were 372, 507, and 521 for the urban, rural-nonfarm, and rural-farm populations, respectively. It should be noted that these figures are not comparable with those shown in tables 18 and 19 because the latter are based on children in the family and women in the household.) Also, a survey taken in April 1949 indicated that fertility (as measured by standardized rates) was higher in the families of farmers and farm managers than for any other major occupation group except farm laborers and foremen. (See U.S. Department of Commerce, Bureau of the Census, Current Population Reports, *Marital Fertility: April 1949*, Series P-20, No. 27, February 1950.)

DEGREE OF DEPENDENCE ON AGRICULTURE

Some of the problems in defining farm population and the use by other countries of the concept of economic dependence on agriculture were mentioned earlier in this chapter. Because a good operational definition of farm population is of primary importance, one of the objectives of this project has been to obtain some data relative to the use of the concept of dependence on agriculture.

Several tabulations relative to dependence on agriculture have been made. From these tabulations, an attempt will be made (1) to explore and analyze alternative definitions of farm population and (2) to measure gradations in degree of dependence on agriculture. The following four questions from the Census of Agriculture questionnaire were used as the basis of these tabulations:

1. "How many days did you work last year off your farm? Include work at a nonfarm job, business, profession, or on someone else's farm . . ."
2. "Did any other member of your family living with you have a nonfarm job, business, profession, or work on someone else's farm last year?"
3. "Did you have any income last year from any of the following sources—sale of products from land rented out, cash rent, boarders, old age assistance, pensions, veterans' allowances, unemployment compensation, interest, and help from members of your family?"
4. "Was the income which you and your family received from work off the farm and from other sources . . . greater than the total value of all agricultural products sold from your place last year?"

Supplementary information was used to determine the classification for most of the cases where information was not given in response to the last two questions. The number of farm operators classified on the basis of this supplementary information totaled 419,000 or 7.9 percent of all farm operators.

Table 20 shows a detailed distribution of farms and of the farm-operator household population by the operator's response to the above questions. Almost two-fifths of the population in farm-operator households were completely dependent on their farm income—neither the operator nor any of his family worked off the family farm and the operator did not have any income from outside sources. (No account has been taken of the work or income of the roughly 300,000 persons 14 years of age and over in farm-operator households but not in farm-operator families.) This

group is the solid core of those economically dependent on agriculture. In addition, about 28 percent of the farm-operator household population were primarily dependent on their farm income, the value of farm sales being greater than family income from other sources. Of the remainder, for which the value of farm sales was less than family income from other sources, 37 percent were in households where the farm operator worked off the farm less than 100 days. In these cases, the farm income may have been less than income from the outside source because of crop failure or some other unusual reason.

LIMITATIONS OF THE DATA

The nature of the sample, definitions, and limitations of a general nature are discussed in the Introduction to this report. This section relates only to certain limitations of the data used in this chapter.

Children under 14 years of age.—Data on the number of children under 14 years of age in farm-operator households were not tabulated. Therefore, in the farm-operator household population tables, data on the number of children under 14 years of age in farm-operator families have been used. Inclusion of persons under 14 years in farm-operator households but not in farm-operator families would have increased the total farm-operator household population by approximately 57,000. Thus, the total farm-operator household population has been understated by about 0.3 percent and the population under 14 by about 0.9 percent. Inclusion of these children would have lowered the median ages and decreased the percentages of persons 14 years old and over.

Distribution of the population under 14 years of age, by sex.—As data on persons under 14 years of age, by sex, were not tabulated, the distributions by sex of persons in this age group, shown in several of the tables, are estimates based on the percentage of males and the percentage of females in the rural-farm population, by age and by regions, for April 1950. Median ages by sex for the farm-operator household population are, of course, based on these estimates.

Age not reported.—When the age of a person was not reported in the Population Census, it was estimated on the basis of other available information. In most cases, these estimated ages were entered on the schedules. In some instances, however, the estimated age was not entered on the schedule but was punched directly on the tabulation cards. The latter group was tabulated as "age unknown" for this report. As this represented only a residual group of an already small number of cases of age unknown, it has been distributed proportionately among persons 20 years of age and over.

In the Census of Agriculture, age was not estimated for those operators of unknown age. In order to estimate the age distribution of members of the household other than operators, shown in table 4, operators of unknown age have been distributed proportionately among the various age groups of operators with age reported. In preparing this table, two other assumptions had to be made. One was that all operators were 14 years of age or older. The second assumption concerned the 39,000 farm operators for whom population information was not available. These operators and other members of their households are not represented in the data on the farm-operator household population; therefore, these farm operators had to be taken out of the age distribution of operators prior to subtraction to obtain the age distribution of non-operator household members. The number of such operators was small.

Therefore, the total number of farm operators shown in table 4 is 5,341,190 rather than 5,380,127—the total number of farms and farm operators shown elsewhere in this report. (The

¹Includes only farm-operator households for which population data are available.

latter figure differs slightly from the final count of farms and farm operators in the 1950 Census of Agriculture because of rounding of the expansion factors used in processing the sample data.) The figure 5,341,190 (and comparable figures for its components) has been used in other tables where data on operators from the Population Census are shown or where comparisons are made between farms and population or operators and population.

Fertility ratios.—As noted on the tables, the fertility ratios are also based on data for children in farm-operator families and for women in farm-operator households. The figures on total women include proportionate shares of the women tabulated as of unknown age. Because necessary data on women by age and

marital status were not available, all women of unknown age allotted to ages 15 to 49 years were assumed to be single.

The age-specific rates are based largely on tabulations of children by age of mother in households containing only one woman ever married—assuming that this woman was the mother of all of the children in that family. The distribution of children by age of mother in households containing two or more women ever married was estimated indirectly from age-specific rates for women ever married in households containing only one woman of this marital status. About 306,000 children under 5 years of age, or 17 percent of all children of this age, were in households containing two or more women ever married.
