RATIO ESTIMATES

It is possible to make an improved estimate of an absolute number based on a sample (improved in the sense that the standard error is smaller) whenever the class in question forms a part of a larger group for which an estimate based on this sample and a complete count are both available. (Complete counts for the detailed occupations and industries appear in Volume II of the 1950 Census of Population.) This alternative estimate is particularly useful when the characteristic being estimated is a substantial part of the larger group; when the proportion is small, the improvement will be relatively minor. The improved estimate (usually referred to as a ratio estimate) may be obtained by multiplying a percentage based on sample data by the figure which represents the complete count of the base of the percentage. An alternative method is to multiply the sample estimate by the ratio of the complete count to the sample estimate of the larger group.

The effect of using ratio estimates of this type for data shown in this report is, in general, to reduce the relative sampling variability from that shown for an estimate of a given size in table C to that shown for the corresponding percentage in table D. Estimates of these types are not being published by the Bureau of the Census because of the much higher cost necessary for their preparation than for estimates derived by multiplying the sample results by 30.
