

PART III.—ORIGINAL STATISTICS.

SOURCES OF ORIGINAL STATISTICS.

44. The population statistics upon which these life tables are based are the census returns for January 1, 1920. Practically all the birth and mortality statistics used were compiled by the Bureau of the Census. The exceptions to this rule are shown in Table 16. Only the total number of deaths by color and sex in Buffalo in 1919 and 1920, and in Cleveland and Detroit in 1919 could be obtained, whereas deaths by color, sex, and age groups as compiled by the Bureau of the Census were needed to render life tables for these cities comparable with those for other cities.

Accordingly certain registrars were requested to furnish the mortality statistics for whites and for Negroes separately by sex for the following age groups: single years of age under 5 and the quinquennial age groups 5-9, 10-14, and so on, to age 100 and over. When the totals for deaths by sex and color furnished by the state did not agree with those compiled by the Bureau of the Census, the totals compiled by the Bureau were distributed into age groups proportionately to those furnished by the state department.

Since birth statistics by sex and color for many other states and cities were not available for all the years 1916 to 1920, it was necessary either to vary the method of computing rates of mortality at ages under 3 years or else to estimate the sex and color distribution of the births. After studying the statistics which could be obtained, it was decided not to vary the method of computing rates of mortality at ages under 3 years, but to use the birth statistics which were available and then to distribute these by sex and color according to the birth statistics of

later years, or according to computed number of births for these years derived from population and death statistics. This last method was necessary only in the case of Chicago, Illinois, and New Jersey. It will be noted that it was necessary to make these distributions by sex and color for only a few areas in the years 1919 and 1920. Since only the differences between births in 1916 and 1918, 1917 and 1919, 1918 and 1920, were required by the formulas used, the errors introduced by these estimated distributions must be very small for the years 1916 to 1918.

For a few areas it was necessary to take from the state reports the deaths under 1 year of age in 1916 by sex and color or to estimate the distribution by sex and color of the total deaths under 1 year of age from state reports. In the case of Illinois the deaths under 1 year of age in 1916, and under 1 and from 1 to 2 years of age in 1917 had to be estimated from those in Chicago for these years. However, since but little weight is given to these deaths in the formulas it was possible to estimate for large areas with only slight errors in the rates of mortality under three years of age.

The populations and deaths at unknown ages are distributed in Tables 17 and 18, pages 58 and 62. This distribution was made by the usual method. That is, the population in each age group was multiplied by the constant ratio of total population to population at known ages to distribute the population at unknown ages among those of known ages, and the deaths at unknown ages were distributed among those of known ages by the same process.
