

CHAPTER IV

REGIONAL DIFFERENTIATION OF THE AGRICULTURE OF THE UNITED STATES

Importance of such a differentiation.—In no country in the world, probably, is there found such a wide range of soil, climate, and topographic conditions as in the United States. This wide variation in physical conditions has resulted in an equally varied agriculture, so varied is it, in fact, that there is no term which can be used that will adequately describe it as a unit or a whole. It has to be broken up into segments and considered by specific kinds and types.

For certain purposes a differentiation of the United States into broad general regions, such as the Corn Belt, the Cotton Belt, the Hard Winter Wheat Belt, and the like will be sufficient. This will indicate the principal regions of the country within which the type of agriculture followed is essentially the same in its common characteristics. Such a differentiation, however, is not refined enough for purposes of detailed study. What is needed is a classification which gets down to counties and local areas and discloses the kind of agriculture found there and at the same time indicates how it varies from farm to farm.

Within broad regions there will be found smaller areas or localities which follow types of farming distinctly different from the region as a whole. Likewise, within even one of these smaller areas, the prevailing crop and livestock enterprises are combined into farming systems differently as we shall see presently. (See Ch. VI).

Difficulties in selecting a basis for regional differentiation.—To select a basis for differentiating the agriculture of the whole country is a very difficult problem. In order that the resulting areas may be consistent one with the other it is important that the same basis be used throughout. It should be constant, not only, from region to region but at the same time should show the relative importance of the different enterprises grown in a particular area.

There also is the additional problem of deciding how much variation will be permitted within the areas differentiated. Obviously, it will be impossible to divide the country into areas that are completely uniform and homogeneous. There are few, if any, areas which are completely uniform in soil and other physical conditions. Economic conditions likewise do not affect all producers the same way, and producers themselves differ with respect to aptitudes, likes and dislikes. A classification has to be adopted, therefore, which will result in a differentiation of areas that are as nearly homogeneous as possible, consistent with the data available and with a practical application of the results.

For the most part, investigators in this field have had to rely largely upon data collected by the census. Up until the 1930 Census, these data consisted largely of unclassified county group totals. Type of farming areas or regions were differentiated on the basis of these totals.

The procedure usually followed, as was indicated briefly in the introductory chapter, was to base the classification on similarity in crop and livestock combinations. Counties were considered to have the same type of farming and were thrown together into areas if they showed the same proportion of crops and livestock. These relatives or coefficients, usually, were computed by relating the acreage in each crop in each county to the total land area, area in farms or area in crops plus pasture. The relative importance of each class of livestock in turn was indicated by showing the number per square mile, per hundred acres of land in farms, or in crops.

There are a number of difficulties with this method of approach. In the first place it fails to give a satisfactory measure of type. To assume that two counties have the same type of farming because they have the same proportion of their total farm area in the same crops obviously may be misleading. It assumes a uniformity within the counties that may not exist. Significant variations may be smoothed out entirely in the totaling process. It is just as significant, or more, to know the dispersion within the area as it is to know the dominant type.

In basing the differentiation upon an area basis the problem of what base to use in computing the relative importance of different enterprises, furthermore, is quite important. In a relatively homogeneous area like Iowa, it is not so difficult, but in States or regions not so uniform it is very difficult. If crop area is used, the relative importance of particular crops will be over emphasized in range livestock areas as compared with farming areas. If farm area is used the same problem arises. Enterprises will appear to be relatively more important than they actually are in areas in which much of the land in farms is nontillable, as compared with areas with the same proportion of the land in farms but with a much higher percentage of it tillable. If land area is used as the base the same difficulty is accentuated.

The problem of intensity of production is even more important. Two enterprises may occupy the same proportion of the farm area yet be decidedly different in relative importance. The enterprise which is produced most intensively will likely represent a much higher proportion of the income and will be relatively most important. Enterprises, intensive by nature, will be underemphasized and will appear of less significance in the farming system than they really are when determined on an area basis.

It is obvious therefore that the use of area as the basis for determining relative importance of enterprise between States and regions with diverse conditions and producing enterprises of varying degrees of intensity is open to serious limitations and may give misleading results.

Basis of differentiation used in this study.—Most, if not all of the foregoing difficulties have been met and taken care of in this study. The method of approach used in differentiating type of farming areas is exactly the reverse of those used in most of the former studies. Whereas the approach in those studies was from a group basis in which unclassified county totals were used, the approach in this study is from the individual farm.

Each farm was first classified by type and then the type of farming areas were determined by a building up process from the individual farm. Thus each type of farming area was determined on the basis of the relative importance of a particular type of farming within it.

The relative importance of a particular type of farming in an area was determined in part by the relative number of particular types prevailing and in part by the relative income from each particular source. Of these two, income was given the more weight. Why this was necessary will be made clear by the following discussion.

A mere count of farms may be misleading, in fact just as much, or more, as determining relative importance on an area basis. This arises from the fact that farms vary widely in size and in intensity of production. In the irrigated areas of the Mountain States, for example, often a small area of irrigated land will show more farms of a highly intensive nature than an area many times its size will show when devoted to range livestock production.

If such areas are differentiated entirely on a count of farms by type, obviously the small farms may be given a weight far beyond their real importance. Income from the different sources under such conditions will show the relative

importance of the different types of farming much more accurately. This in fact is the big advantage which income, as a base for differentiating areas, has over other bases. It provides a common denominator to which the relative importance of all enterprises can be reduced.

But even income can not be accepted blindly in determining relative importance. It must be interpreted in the light of the intensity of production of the different enterprises; also in the light of the importance of an area from an agricultural standpoint. For example, two areas may show the same proportion of their total income from the same sources yet one be entirely different from the standpoint of agricultural importance, yields, practices and the like.

Thus, in addition to income by source and count of farms by type, other factors were taken into consideration in differentiating type of farming areas. Among these were included the proportion of the land area in farms and of the farm area in pasture and in the different crops, production of the important crops and number of the important classes of livestock per square mile, yields, tenure of operator (in the South), expenditures for fertilizer, and of course soil, topography and climate. The character of the vegetation in the range livestock areas also was given weight. These factors served as a very valuable check upon the use of income and count of farms by type in the area differentiation.

The initial task in differentiating the United States into type of farming areas, of course, had to do with the getting together of these data, resolving them into relatives and coefficients and getting them onto maps and charts for study. This in itself was a big undertaking.

This information was first assembled and charted for all the counties in the United States. It soon became evident that county data alone would be of limited value in differentiating type of farming areas for many regions of the United States. This was particularly true of the 11 Western States, for the New England and Middle Atlantic States, Maryland, Florida, West Virginia, and parts of Virginia, Kentucky, Tennessee, and many of the other States. Accordingly, a count of farms by type for townships was made for these States. Township data of the same character were also obtained for township adjacent to the more important urban areas and in areas devoted to specialized farming of one kind or another in most all of the States so as to add refinement to the classification.

The generalized type of farming map of the United States.—The differentiation was first made by States and then fitted together onto a United States map. With the exception of some of the Middle Western States, where the author had already made type of farming studies, all of the State maps were sent to representatives of the various State agricultural colleges and experiment stations for criticisms and suggestions.¹ In the light of these criticisms the map was then reworked and refined before final drafting. The map as it appears in final form is shown in the pocket envelope attached to the inside of the back cover page. An examination of the map will disclose that the agriculture of the United States has been differentiated into 514 major type of farming areas and into many additional subareas.

The exact basis of differentiation was determined by the dominance of a particular type or income from a particular source or combination of same. Variation in physical conditions also were given a good deal of weight, particularly as they were reflected in income and in production per square mile of the important crops and number per square mile of the different classes of livestock.

¹ The author is much indebted to the representatives of these agencies for the many helpful suggestions and criticisms made by them, and he hereby wishes to express his thanks and appreciation.

Dominance of a particular type was determined on the basis of whether it represented the major type in the area or whether it represented the major source of income. Unless a particular type represented 35 to 40 per cent or more of all the farms or the income from that one source represented the same proportion or more the type of farming was not considered dominant in the area.

A combination code was given to areas in which the principal source of income came from two sources provided the two made up at least 50 per cent or more of the total number of farms or income and provided further that a third source was less than half of the lowest of the two.

The map would be much more graphic if a different crosshatching had been used for each distinct combination. This was impossible because of the limited number of crosshatchings available. The ideal arrangement, of course, would have been to print the map in color. Then the combination types would have appeared as a blend of the two main types comprising it.

Where the income was from a large number of sources on the same farms, none of which was dominant or where there were a large number of different types represented in the area, the area was given a general or mixed code in the crosshatching. It would have been preferable to keep the general-farming areas distinct from the mixed-farming areas, but since the number of codes for crosshatching was limited it was decided to use the one code for both.

The two, however, are distinct. General farming areas are those in which a large number of sources of income are found on the same farm none of which is dominant, i. e., represents as much as 40 per cent of the income. Mixed farming areas on the other hand are those which have a large number of distinct types of farms. They may have as many sources of income as found in general farming areas, but the difference is that these sources appear not on the same farm but on distinct types of farms. A good example of a mixed farming area is the Willamette Valley of Oregon and of a general farming area is in the central basin of Tennessee or in east central Ohio.

In further explanation of the map, it will be noted that self-sufficing, part-time and forest product areas have been given the same crosshatching. This again was done to keep the number of codes at a minimum. In determining combination codes these also were treated as a unit. Mountains, deserts, swamps, and areas having but a limited agriculture have been given the same code. Areas having this crosshatching either have no agriculture or it is so scattered as to be of relatively little importance.

The description of the agriculture in each major and subarea because of the limited space on the map necessarily had to be brief. In fact it may be so short as to be misleading in some cases. It furthermore does not show satisfactorily in many cases why the area was differentiated.

For a more complete characterization of the type of farming areas the reader is referred to Tables 2 to 7. These tables are based on samples taken from representative counties or townships in each area and are therefore approximate and not an exact characterization. A slightly different per cent of income, of type, of acreage, and of production would result were the characterization based on all the counties or townships in the areas shown or if taken for other sample counties or townships in the areas. The difference, however, would not be large and the characterization as shown may be accepted as being substantially correct. A small difference is of no significance, any way, inasmuch as it would not alter materially the general picture.

An examination of the tables will show that the information on income, acreage, and production for the Pacific and Mountain States particularly, and to a lesser extent for the New England and Middle Atlantic States is not nearly so complete as for the North Central, East South Central, South Atlantic, and West South Central States. This arises from the fact that the differentiating of these States was based largely on township data. Information on income, production, and acreage of the important crops was not available by townships and therefore could not be shown except where a complete county was in the area and a county total could be used. Wherever complete data for all of these items were available they were shown.

In some of the States only a rough count of farms was made by townships to determine what were the prevailing dominant types of farming. This was particularly true of Washington and Oregon and in some of the Mountain States. The failure to report a particular type of farming in some of the areas should not be construed as meaning that this particular type is not found there; it may be, but it is relatively of much less importance than those shown.

The same is true for certain of the crops. No attempt was made to show the complete utilization of the land in each area. Only the more important of the crops are shown in most cases so the percentages will not add to 100 per cent.

The income will be found to be reported more completely. It will be noted, however, that it is designated "Approximate per cent of income by source." This was so designated for the reason that a certain amount of estimating had to be done. The published census reports do not show income broken up into as much detail as here shown. For the purpose of the differentiation, as well as for the characterization, it was important to show income by source in as much detail as possible, and to do so a value for certain of the items had to be computed. This was done by applying the average prices compiled by the Department of Agriculture in cooperation with the Bureau of the Census to the quantities sold or to be sold. These computed values were then related to the total value of all products sold, traded, or used by operator's family as given in the reports by type of farm to obtain the percentages shown.

With this brief explanation of the tables there should be no confusion as to what they include. The information in them, in fact, is self-explanatory. Each line represents the characterization of the agriculture in each type of farming area. The tables should be very helpful in interpreting the map and in disclosing the basis for the differentiation of the different areas. A study of them will show that the subareas are based on variations within the larger area. Often-times this difference is not marked, but it was deemed sufficiently large to warrant further distinction.

Before concluding the discussion of the type of farming areas and the map, attention should be called to lack of refinement in the map in certain parts of the country. The differentiation of the type areas in Florida, probably in many respects, is the least satisfactory of any of the States. This resulted because of the extremely spotted character of the farming in that State. The differentiation of areas in a map of the scale here shown necessarily may designate areas as having a particular type of farming which include large areas of swamp or nonagricultural land. To map such regions properly it will be necessary to use a map on a different scale also to obtain more detailed data. Data by townships fail to show the proper localization in many cases.

Situations of a similar nature although not quite so extreme were found in other States. Within some of the areas as mapped may be found small localized areas that differ considerably from the larger areas.

TABLE 2.—CHARACTERIZATION OF TYPE OF FARMING AREAS, PACIFIC STATES

¹ Corn, oats, and barley.
² Wheat, rye, flax, and rice.
³ Other crops usually grown for sale.

TABLE 3.—CHARACTERIZATION OF TYPE OF FARMING AREAS, MOUNTAIN STATES—Continued

[Data are shown only for principal items or types; when not included it does not necessarily mean that there were no such items or types reported]

TYPE AREA NUMBER	Per cent of total land area in farms	PER CENT OF FARM LAND IN—							LIVESTOCK PER SQUARE MILE OF TOTAL LAND AREA								
		Irrigation	Pasture	Crop land	Feed grain	Hay	Cash grain	Other cash crops	Cows kept mainly for milk	Cows kept mainly for beef	Yearling steers and bulls	2-year old steers and older	Other cattle	Sows and gilts	Sheep	Goats	Chickens
