

Accuracy of Data on Population Characteristics for Subgroups of the Total Population

I. Introduction and Background

As one of a series of reports for the evaluation of the 1960 Censuses of Population and Housing, measures of response variance and bias for selected population and housing characteristics are presented (see Series ER60, Nos. 3, 4, 5, and 6). These measures were derived from a comparison of two responses for the same individuals or housing units relating to the same characteristics at the same point in time. The first response in all cases was the census response; the second, was either the result of a reinterview, or from an independent record pertaining to the person or unit.

In the estimates in this report, the basic data are those used in ER60 No. 4, Accuracy of Data on Population Characteristics as Measured by Reinterviews. Reinterviews were conducted after the census in the Content Evaluation Study (CES) in a sample of about 3,000 households with approximately 10,000 persons. The census responses were compared with the reinterview responses, and when differences occurred, the respondent was asked to explain the difference. Comparisons between the original census response and the reconciled reinterview response were presented for several population characteristics. Measures of the simple response variance and bias were derived for these characteristics.

There are serious problems in estimating the simple response variance and the bias from the same data. The gross difference rate, which is the average over all units in the study of the square of the difference between the original interview and the reinterview, is used as a measure of the simple response variance. If the original survey and the reinterview are conducted independently and the general conditions of the two surveys are the same, then the gross difference rate divided by 2 is an unbiased estimate of the simple response variance, as shown by Hansen, Hurwitz, and Pritzker [6]. The same type of interviewers, the same questionnaire, and the same kind of training should apply to both situations. Thus, to estimate the simple response variance, all conditions in the reinterview should be as nearly as possible identical to the original interview.

Even under the best possible circumstances, there is probably some "conditioning" of the unit as a result of the unit having been observed previously. Usually there is an underestimate of the simple response variance. Any attempt to make the reinterview a better procedure than the original interview biases the estimate of the simple response variance. Thus, when a better questionnaire is

used in the reinterview, when better interviewers are employed, and when reconciliation of responses is accomplished, the result is a biased estimate of the simple response variance. It has been shown in [1] that by reconciling responses, we underestimate the simple response variance by 5 percent to 40 percent, depending on the characteristic.

On the other hand, in order to measure bias, we need the best possible answers in the reinterview. Probing questions by better interviewers may help, and reconciliation of responses may help. All of the things that cause difficulty in estimating the simple response variance may help in estimating the bias.

However, in spite of these difficulties, reports have been issued giving estimates of both simple response variance and bias computed from the same data. The previous reports essentially contain measures only for the total population. The present report contains comparable data for subgroups of the population and aid in interpreting the data. For example, an estimate of the simple response variance for the category "highest grade of school completed, 8 years of elementary school" is .042 for the population as a whole. Questions arise on whether some subgroups account for a disproportionate share of the total. Does it vary by geographic region of the United States? Does it vary among racial groups? Similar questions pertain to all population characteristics studied. These questions are of major importance to sociologists, demographers, and survey researchers who are interested in the consistency of response to given items and in the bias in census items.

In this report, measures of simple response variance, shown as an index of inconsistency as well as bias, are shown for several subgroups of the population for four population characteristics--educational attainment, residence in 1955, number of children ever born, and total personal income.

In section II of this report, the measures of simple response variance and bias are discussed. Also an index of inconsistency, which indicates the amount of inconsistency one can expect in the responses of identical individuals on different occasions to the same question, is presented. An L-fold index of inconsistency is shown.

In section III, estimates of the index of inconsistency and estimates of the bias are compared for subgroups of the population for each of the four characteristics studied.

II. Measures of Simple Response Variance and Bias

By conducting reinterviews after a census or survey, two sets of data on selected characteristics for identical persons are obtained. Diagram 1 is one way in which the results of a census and a reinterview may be presented for a given category of persons whose income is in the range of \$5,000-\$5,999.

Diagram 1. RESULTS OF CENSUS AND REINTERVIEWS FOR IDENTICAL PERSONS

Reinterview	Census		
	Income, \$5,000-\$5,999	Income, not \$5,000-\$5,999	Total
Income, \$5,000-\$5,999.....	a	b	a+b
Income, not \$5,000-\$5,999.	c	d	c+d
Total.....	a+c	b+d	n=a+b+c+d

The diagram shows that "a" persons were reported in the income group \$5,000-\$5,999 in both the census and the reinterview; "c" persons were reported in that income group in the census, but not in the reinterview.

If everyone were reported identically in the census and the reinterview, then "b" and "c" would both be zero. This indicates that there is no variability in response when individuals are asked the same question on different occasions, so that the simple response variance is zero. As b and c get larger, there is less of a tendency for consistent responses, and the simple response variance is larger.

The gross difference rate "g" is the number of differences in responses between the census and the reinterview divided by the total number of cases, i.e.,

$$g = \frac{b+c}{n} \quad (1)$$

As mentioned earlier $g/2$ is an unbiased estimate of the simple response variance when the census and reinterview are conducted independently and under the same conditions.

In reality, these conditions will never be met, since the reinterview cannot be made independent of the census interview. In particular, in the Content Evaluation Study, since the census and reinterview responses were reconciled, the reinterview response was not independent of the census response. In this case, we get underestimates of the simple response variance, the magnitude of the underestimation varying by subgroup of the population. Nevertheless, we shall use $g/2$ to estimate the simple response variances for these subgroups.

In addition to the simple response variance, we are also interested in estimating the bias of the census response for an item. In order to use the reinterview to make an estimate of the bias, we shall assume that the responses to the reinterview are more accurate. In other words, we accept the reinterview as a standard against

which we measure the census. This assumption is partially justified by the fact that for the reinterview a questionnaire with more probing questions was used; more experienced interviewers were employed; and the reinterview for each person was conducted, where feasible, with the sample person himself, instead of a proxy respondent. Further, when differences in response between the two interviews were observed, the differences were "reconciled," that is, the respondent was asked to explain the difference. The reinterview data shown in this report are those obtained after reconciliation of response differences.

The bias is then estimated by the net difference rate, \bar{e} , i.e., the difference between the proportion of cases reported in the census and the proportion reported in the reinterview. In the notation of diagram 1,

$$\bar{e} = \frac{a+c}{n} - \frac{a+b}{n} = \frac{c-b}{n} \quad (2)$$

When \bar{e} is negative, there was an understatement in the census; when \bar{e} is positive, there was an overstatement in the census. For example, the net difference rate for persons reporting no personal income in 1959 was .05. This means that of persons reporting on income at both the census and the reinterview, 5 percent more persons reported no income in the census than in the reinterview.

Now, suppose that the gross difference rate is .084. Half this value, or .042, is an estimate of the simple response variance. However, it is difficult to compare simple response variances because their magnitudes depend on the proportion of the population in the given category (diagram 1). Instead, it is desirable to work with an index of inconsistency which is much less subject to this defect.

In what follows, we shall ignore the effects of any correlated component of response variance which is due to interviewers, coders, crew leaders, etc. Thus, we shall assume that the total variance of a statistic is the sum of the sampling variance and simple response variance. (See Hansen, Hurwitz, and Pritzker [6].) The index, I, is defined to be the simple response variance divided by the total variance which is equal to PQ where P is the proportion of the population in the given category and $Q=1-P$. We estimate it by

$$\hat{I} = \frac{g/2}{s^2} \quad (3)$$

where s^2 is an estimate of PQ . There are several alternative estimates of PQ . However, we have taken as an estimate for PQ the average value computed from the two sets of responses. In the notation of diagram 1,

$$s^2 = \frac{1}{2} \left[\left(\frac{a+c}{n} \right) \left(\frac{b+d}{n} \right) + \left(\frac{a+b}{n} \right) \left(\frac{c+d}{n} \right) \right] \quad (4)$$

where $p_1 = \frac{a+c}{n}$ is the estimate of P from the census and

$p_2 = \frac{a+b}{n}$ is the estimate of P from the reinterview.

Thus s^2 can be written somewhat easier as

$$s^2 = \frac{1}{2} [p_1 q_1 + p_2 q_2] \quad (5)$$

It has been shown by Hansen, Hurwitz, and Bershada [5] that under certain general conditions PQ is the sum of the simple response variance plus the sampling variance. Thus, as I becomes larger, a greater proportion of the total variance is due to variability in response. This accounts for the name of the index; as I increases, the item shows more and more inconsistency. Cochran [4] points out that $1-I=R$, which in psychometric scaling is sometimes called the coefficient of reliability since it is the correlation between two independent measurements of the sample units by two different judges or scalars.

In the previous example, the simple response variance was estimated to be .04. Suppose that the estimate of I is .30. This would be interpreted to mean that the simple response variance for this item accounts for about 30 percent of the total variability of the item. Many of the estimates of I for income categories are over .50, indicating that over half the total variance associated with these items is contributed by the simple response variance.

In the results which follow, we show estimates of I for different characteristics for different subgroups of the population. Tepping [7] has shown that for small sample sizes, less than 100, or when the proportion of the population in a given category is small, .01 or less, the estimates of I are badly biased and have large sampling variances. Thus, indexes are not shown for these cases. For other cases, when the sample size is small and the index is large, estimates of the index are biased upward. In these cases, the estimated standard errors are underestimates and we do not show them. For the other characteristics, we show estimates of I with their sampling errors. We also show an L-fold index of inconsistency, which is a weighted average of the individual indexes. The weights are the values of PQ for the categories considered. A discussion of this L-fold index is given by Bershada in [2].

We also show estimates of the bias for different characteristics for different subgroups of the population, along with estimates of their sampling errors. In some cases the proportion of the population in a given category is zero. Then, the estimate of the bias is zero, and the estimate of the standard error of the bias is also zero. The reader should be cautious in the interpretation he makes of these estimates.

The sampling error of the estimate of the index of inconsistency has been approximated by using a linearization technique. By expanding the expression for the index of inconsistency in a Taylor series, we use the variance of the linear term in the expansion as an estimate of the variance of the index of inconsistency. Tepping [7] has shown that for most cases this estimate has a very small bias and a small sampling error, for reasonably large samples.

To simplify somewhat the expression for the estimate of the variance of the index, we shall rewrite the index from equations (3) and (4) in terms of the proportions

$$p_1 = \frac{a}{n}, p_2 = \frac{b}{n}, p_3 = \frac{c}{n}, p_4 = \frac{d}{n}$$

Then

$$\hat{I} = \frac{p_2 + p_3}{(p_1 + p_2)(p_3 + p_4) + (p_1 + p_3)(p_2 + p_4)} \quad (6)$$

The linear approximation to \hat{I} is

$$I + \sum_{i=1}^4 p_i \frac{\partial \hat{I}}{\partial p_i}$$

where I and $\frac{\partial \hat{I}}{\partial p_i}$ are evaluated at the expected values

$E p_i = P_i$. The variance is then approximated by

$$d' A d \quad (7)$$

where d is the vector of derivatives $\left(\frac{\partial \hat{I}}{\partial p_i}\right)$, d' is its

transpose, and A is the variance-covariance matrix

of the p_i , namely $[\text{Var}(p_i, p_j)]$. Substitution of sample estimates for the elements of (7) then yields an estimate of the variance of \hat{I} . In this report, we have assumed simple random sampling so that we have taken the estimate of the variance-covariance matrix to be given by

$$\text{Var}(p_i) = \frac{p_i(1-p_i)}{n}$$

$$\text{Cov}(p_i, p_j) = -\frac{p_i p_j}{n}$$

and have estimated the vector d by substituting the sample estimates p_i in the analytic expressions for the derivatives.

We also estimate the variance of the bias estimate. The variance of the bias estimate is

$$\text{Var}(\bar{e}) = g/n \quad (8)$$

where g is the gross difference rate and n is the sample size. The derivation of this estimate of the variance of the bias is discussed by Bershada in [3],

III. Detailed Comparisons Among and Within Population Subgroups for Selected Population Characteristics

As mentioned in section I, four population characteristics were selected for study. Each of these characteristics will be discussed in a separate section which follows. In the section for a particular characteristic, the subdivisions of the populations and the approximate sample sizes are given. The sample sizes are small for some subgroups of the population such as Negro and other races by amount of education and number of children. Of course, the question on number of children was limited to women 14 years old and over who had been married. For the total United States there were 2,500 cases included in the reinterview study, of which only 200 were women belonging to Negro or races other than white. When these 200 women are split into categories by the number of years of education, the sample sizes are small. If the sample size is less than 100, we have not estimated the index of inconsistency.

Tables 1 through 91 at the end of this report present the data for the characteristics studied. The responses for each person in the reinterview study were given weights according to the probability of selection of that person. The data for each person were tabulated by his response in the census and his response in the reinterview. The census result is indicated in the boxhead, and the reinterview classification in the stub. For example, in table 1 which shows educational attainment for all persons in the United States who were 25 years old and over, there were 24,955,000 persons classified in the census as having completed 4 years of high school. Of these, 55,000 did not report their age in the reinterview; 132,000 were classified as under 25 years old in the reinterview; 343,000 did not report their educational attainment in the reinterview. A total of 24,425,000 of the original total were classified by educational attainment in the reinterview, and 21,325,000 were classified in the same category as in the census.

Occasionally, there are differences in the totals for persons in a given age group depending on the characteristic under study. The reason for this is that information relating to the statistic was used in determining the age for that table. The differences are quite small.

In making estimates of the index of inconsistency and of the bias, only the information pertaining to persons who responded in both surveys is used. Thus, if a person did not answer a question in the reinterview, the data for that person are not used in the estimates. In tables 1 through 91, heavy lines outline the portion of the table in which there were two responses for each individual. The numbers underlined are the cells for which there was agreement between the census and the reinterview.

A. Educational Attainment

Tables 1 through 7 show data classified by responses to questions on educational attainment in both the census and the reinterview for all persons 25 years old and over for the following areas and subgroups of the population:

Table	Area or subgroup of population	Approximate sample size
1	Total United States	5,000
2	Northeast region	1,300
3	North Central region	1,600
4	South region	1,400
5	West region	700
6	White population	4,500
7	Negroes and other races	500

Table A shows the indexes of inconsistency by geographic region and by race. The estimated standard errors of the indexes are shown with the indexes. A number in the table such as $.24 \pm .03$ means that the index of inconsistency was $.24$ with a standard error of $.03$.

Table A. Indexes of Inconsistency and Their Standard Errors for Educational Attainment, by Population Subgroup

Educational attainment	United States	Geographic region				Racial group	
		Northeast	North Central	South	West	White	Negro and other races
No school years completed.....	.24±.03	.20±.05	.35±.09	.27±.06	.10±.07	.21±.04	.31±.08

5 years or more.....	.17±.02	.16±.05	.09±.03	.24±.06	.21±.06	.17±.03	.26±.13
Average I.....	.31	.31	.30	.32	.29	.30	.40

NA Not available. Indexes of inconsistency are not estimated for categories which contain 1 percent or less of the population under study.

A general rule of thumb used in the interpretation of these indexes is that indexes of less than .20 are small, those between .20 and .50 are moderate, and those over .50 are large. For characteristics such as age the indexes are small, usually less than .10, indicating that response variability is not a major problem for these items. For educational attainment, the indexes generally lie between .20 and .40, indicating that there is some difficulty in reporting consistently. For many income items, the indexes are over .5, indicating that there is a need to improve the question or the data collection method to eliminate the variability in response.

Table A shows that most of the indexes are between .20 and .40. The estimates are precise enough so that we can be quite sure that the indexes are in this range and not much larger or smaller. For example, the estimate of the index for the category "high school 1 year" for the total United States is .40 with a standard error of .02. Thus, we are fairly confident that the index for this category is in the range .35 to .45.

Some comments that can be made about the results shown in table A are as follows:

1. The indexes of inconsistency for "high school 4 years" and "college 4 years" are smaller than those for other categories. This is true for the total United States, for the four regions, for the white population, and for Negroes and other races. The estimates of the index for these categories are about .2. The smaller size of these particular indexes may be related to the fact that these two categories are terminal points for educational achievement. However, tables 1 through 7 show that "elementary 8 years" is also a terminal point, but the indexes for this category are not as small as those for "high school 4 years" and "college 4 years."

2. The estimates of the index of inconsistency are quite similar for the four regions. The estimates for "elementary 1 to 2 years" seem to be higher in the South, and for Negroes and other races. However, this could be due to sampling error.

3. The estimates of the index of inconsistency are generally larger for Negroes and other races than for the white population. This is reflected in the average of the indexes of inconsistency which is .40 for Negroes and other races and .30 for the white population. The indexes are higher for all but three categories, and for elementary school and high school categories are often higher by as much as .10 to .20. For example, for the category "elementary 8 years," the index for the white population is .30, and for Negroes and other races, it is .49. Of course, the sampling errors associated with the indexes for Negroes and other races are larger than those for the white population because of the smaller sample size.

4. The average indexes, average \hat{I} , over all categories, are almost identical for the four regions and the total United States.

Table B shows estimates of the bias for educational attainment items. Most of the estimates are extremely small. It has been noted in other Census Bureau publications that a reinterview is not a very effective method for estimating bias. If a person did not understand the question, did not know the correct answer, or withheld information at the initial interview, he is likely to make the same error in a reinterview. Comparisons with data collected for administrative records such as tax returns, Social Security records, and other such records are more likely to be useful in estimating biases.

Table B. Estimates of Bias and Their Standard Errors for Educational Attainment, by Population Subgroup

Educational attainment	Proportion of persons in category in census, for total United States	United States	Geographic region				Racial group	
			North-east	North Central	South	West	White	Negro and other races
No school years completed.....	.020	.000±.001	.001±.003	-.005±.002	.004±.003	.000±.002	.000±.001	-.005±.008

2 years.....	.040	.005±.002	.009±.004	.002±.004	.001±.005	.012±.006	.005±.002	.002±.004
3 years.....	.019	.001±.002	.003±.003	.002±.003	-.004±.004	.009±.005	.001±.002	-.002±.004
4 years.....	.045	-.001±.002	.002±.003	.002±.003	-.002±.004	-.009±.005	-.001±.002	.002±.005
5 years or more...	.029	.003±.001	.000±.002	.001±.002	.005±.003	.009±.005	.003±.001	.000±.005

We show a column with the proportions of persons in the categories listed. These are estimates from the table for the United States. The purpose of the column is to enable the reader to relate the size of the bias to the size of the proportion. A bias of .004 for a proportion of .009 is quite substantial relative to the size of the category while a bias of .004 for a proportion of .069 is much less serious.

A comment on the results shown in table B is:

There seems to be a tendency for people to report closer to the average number of years of education for the United States. Thus, we see that for the total United States, there are negative biases for the elementary school categories and positive biases for almost all of the college categories. The pattern holds reasonably well for the four regions and for the white population.

For the educational attainment characteristic, we do not find many differences between subgroups of the population. The estimates of the indexes of inconsistency were about the same, with some differences between the white population and Negroes and other races. However, both the estimates of the indexes of inconsistency and of the bias for Negroes and other races were based on a sample of 500 so that the sampling errors were larger than for the other subgroups.

B. Residence in 1955

Tables 8 through 35 show data classified by response to the question on residence in 1955, in both the census and the reinterview, for all persons 5 years old and over for the following areas and subgroups of the population:

Table	Area or subgroup of population	Approximate sample size
8	Total United States	8,000
9	Northeast region	2,000
10	North Central region	2,500
11	South region	2,400
12	West region	1,100
13	White population	7,200
14	Negroes and other races	800
15	White, 8 years or less of school	1,600
16	White, 9 to 11 years of school	900
17	White, 12 years or more of school	2,000
18	Negroes and other races, 8 years or less of school	300
19	Negroes and other races, 9 to 11 years of school	100
20	Negroes and other races, 12 years or more of school	100
21	14 to 24 years old	1,400
22	25 to 44 years old	2,400
23	45 years old and over	2,700
24	25 to 44 years old, less than 8 years of school	250
25	25 to 44 years old, 8 years of school	250
26	25 to 44 years old, 9 to 11 years of school	500
27	25 to 44 years old, 12 years of school	900
28	25 to 44 years old, 13 to 15 years of school	250
29	25 to 44 years old, 16 years or more of school	200

Table	Area or subgroup of population	Approximate sample size
30	45 years old and over, less than 8 years of school	800
31	45 years old and over, 8 years of school	500
32	45 years old and over, 9 to 11 years of school	450
33	45 years old and over, 12 years of school	450
34	45 years old and over, 13 to 15 years of school	200
35	45 years old and over, 16 years or more of school	150

Educational attainment was tabulated only for persons 25 years old and over. Therefore, some of the sample sizes for groups by race and education do not add to the total for the race. For example, the total sample size for the white population is 7,200. However, when the white population is split into three groups by amount of education, the sum of the three sample sizes is 4,500. The remaining 2,700 persons are under 25 years old or did not report on educational attainment in the reinterview.

The classification by age and educational attainment is based on the reinterview response. Thus, if a person was reported in the 25 to 44 year age group in the reinterview he is included in the table for that age group even though he was not reported in the age group in the census.

Table C shows the indexes of inconsistency for residence 5 years prior to the census with their standard errors. Indexes are not shown for categories which contain 1 percent or less of the population under study. Thus, no indexes are shown for the category "abroad" for several of the populations.

There are several comments to be made about the results in table C.

1. The indexes are generally in the range we consider to be small. For the total United States, none of the indexes is over .20.

2. The indexes are roughly the same over the four geographic regions.

3. The indexes for Negroes and other races are larger than those for the white population. This is most clearly true for those categories reflecting movement to another county or State.

4. The indexes for the age group of 45 years and over are smaller than those for the two younger age groups.

5. Within a given age group, the level of education did not seem to have much of an effect on the size of the index.

6. Within a given racial group, the level of education did not seem to have much of an effect on the size of the index.

NA Not available. Indexes are not computed for categories which comprise 1 percent or less of the population under study. For cases for which the estimated standard error is shown as .00, the reader is reminded that the standard error is undoubtedly positive.

Table D shows the estimates of the bias with their standard errors for residence in 1955. Some comments on the results shown in table D follow:

1. There seems to be a positive bias in the census estimate of the number of persons living in the same house in 1960 as in 1955. This bias is reflected in the

total United States and all regions except the North Central. Generally, there is an overstatement of about 2 percent in the census estimate.

2. The bias for Negroes and other races for the "same house" category is larger than that for the white population and is probably larger for each educational attainment group.

Table D. Estimates of Bias and Their Standard Errors for Residence in 1955, by Population Subgroup

Note: For cases for which the estimated standard error is shown as .000, the reader is reminded that the standard error is undoubtedly positive.

3. Within a given racial group, level of education seems to have had little effect on the estimates of bias. There may be some exceptions for Negroes and other races, but the estimates have large sampling errors.

4. There is a positive bias in the census estimate of the "same house" category for the 25 to 44 year age group. Within this age group, the bias was about the same for each educational level.

5. The biases for the 45 years and over age group are very small if not zero for all categories. Again, this is consistent over all educational levels.

From an examination of tables C and D we are led to the conclusion that geographic region and educational attainment have little effect on the magnitudes of simple response variances, as reflected in indexes of inconsistency, or on biases. Race and age do seem to have an effect with the white population having smaller simple response variances and biases than Negroes and other races. Older people have smaller simple response variances and biases than the younger age groups.

C. Number of Children

Tables 36 to 63 show the data classified by response to the question on number of children ever born in both the census and the reinterview for females 14 years old and over who had ever been married. Tables were produced for the following areas and subgroups of the population:

Table	Area or subgroup of population	Approximate sample size
58	45 years old and over, less than 8 years of school	350
59	45 years old and over, 8 years of school	250
60	45 years old and over, 9 to 11 years of school	200
61	45 years old and over, 12 years of school	250
62	45 years old and over, 13 to 15 years of school	100
63	45 years old and over, 16 years or more of school	50

We notice that some of the sample sizes are very small. For the three populations for which the sample size is less than 100, the indexes of inconsistency are not estimated.

Table E shows the indexes of inconsistency and their standard errors for the populations studied. Some general comments can be made about the results shown in this table.

1. The general magnitude of these indexes is small. Hardly any were over .20 and many were less than .10. This is a question, moreover, on which we would expect little variability in response. However, if the respondent were someone other than the mother he may be unaware of children born who may have died in infancy.

2. There is not much variation among indexes of inconsistency for different geographical regions.

3. The indexes for Negroes and other races with only one exception (which may well be the result of sampling error) appear to be larger for every category than the corresponding indexes for the white population.

4. Indexes for the population 45 years old and over are larger than for the two younger populations. In fact, though the indexes are relatively small, they are about twice as large for the 45 years and over age group as for the 25 to 44 year age group.

5. Though the indexes are larger for the older age group, this seems to be the case mainly with those having 8 years or less of school. There may also be a difference in the groups with 12 years of education. However, one must keep in mind the possibility of the differences being due to sampling error.

6. Though the data are incomplete, it seems a reasonable hypothesis that educational level made a bigger difference in the sizes of the index of inconsistency than did race or age. Those with 8 years or less of school had larger indexes than the other groups within the white population and for persons 25 to 44 years old as well as those 45 years old and over.

Table	Area or subgroup of population	Approximate sample size
36	Total United States	2,500
37	Northeast region	600
38	North Central region	800
39	South region	700
40	West region	400
41	White population	2,300
42	Negroes and other races	200
43	White, 8 years or less of school	750
44	White, 9 to 11 years of school	450
45	White, 12 years or more of school	1,000
46	Negroes and other races, 8 years or less of school	100
47	Negroes and other races, 9 to 11 years of school	50
48	Negroes and other races, 12 years or more of school	50
49	14 to 24 years old	200
50	25 to 44 years old	1,100
51	45 years old and over	1,200
52	25 to 44 years old, less than 8 years of school	100
53	25 to 44 years old, 8 years of school	100
54	25 to 44 years old, 9 to 11 years of school	200
55	25 to 44 years old, 12 years of school	500
56	25 to 44 years old, 13 to 15 years of school	100
57	25 to 44 years old, 16 years or more of school	100

NOTE: For cases for which the estimated standard error is shown as .000, the reader is reminded that the standard error is undoubtedly positive.

Table F shows the estimates of bias in the estimates of the number of children ever born. Most of the estimates were small and had large standard errors. Some comments on the results shown in table F are:

1. No differences in the level of bias can be detected among the four geographic regions. Though some individual estimates look bigger for one region than for another, the difference may well be attributable to sampling error.

2. The bias seems to be smaller in absolute value for the white population than for Negroes and other races. However, the sampling errors are so large that no definitive statement can be made.

3. The estimates of bias differed very little among the three age groups.

4. Within the group 25 to 44 years old and also within the group 45 years old and over, the biases were very small for most categories for those persons having some college training. This, again, is an indication that level of education has more of an effect on the responses to this question on number of children than age or race.

D. Total Personal Income

The response to this question was obtained by adding together responses to questions on income from wage and salary, income from own business or self-employment, and income from other sources. If one of these items was not answered, than there was also a nonresponse for total personal income.

Table 64 through 91 show the data classified by the sum of the incomes from wage and salary, self-employment, and other sources in both the census and the reinterview for all persons 14 years old and over. It is immediately apparent that there is less consistency in the reporting of this characteristic than in any of the others we have looked at. One reason for this is that the answer to this question--the amount of income derived from three sources--is not as readily available as answers to questions on number of children, residence in 1955, or educational attainment. Most housewives can easily tell you how many children they have had; they may not be able to tell you how much money their husbands made in wages or on the stock market last year. Thus, if you reinterview a different person from the one who filled out the census report, you may get a different answer.

Tables were prepared for the following areas or subgroups of the population:

Table	Area or subgroup of population	Approximate sample size
64	Total United States	6,400
65	Northeast region	1,700
66	North Central region	2,000
67	South region	1,800
68	West region	900
69	White population	5,800
70	Negroes and other races	600
71	White, 8 years or less of school	1,700
72	White, 9 to 11 years of school	900
73	White, 12 years or more of school	2,000

Table	Area or subgroup of population	Approximate sample size
74	Negroes and other races, 8 years or less of school	300
75	Negroes and other races, 9 to 11 years of school	50
76	Negroes and other races, 12 years or more of school	100
77	14 to 24 years old	1,300
78	25 to 44 years old	2,400
79	45 years old and over	2,700
80	25 to 44 years old, less than 8 years of school	300
81	25 to 44 years old, 8 years of school	250
82	25 to 44 years old, 9 to 11 years of school	500
83	25 to 44 years old, 12 years of school	900
84	25 to 44 years old, 13 to 15 years of school	250
85	25 to 44 years old, 16 years or more of school	200
86	45 years old and over, less than 8 years of school	850
87	45 years old and over, 8 years of school	550
88	45 years old and over, 9 to 11 years of school	450
89	45 years old and over, 12 years of school	450
90	45 years old and over, 13 to 15 years of school	200
91	45 years old and over, 16 years or more of school	150

For one subgroup, Negroes and other races with 9 to 11 years of school, the sample size is less than 100. For that population, no indexes of inconsistency are shown.

Table G shows the indexes of inconsistency for the subgroups studied. It is immediately apparent that the total personal income characteristic is much less consistent than the others we have looked at. Most of the indexes are about .5 with some estimates going as high as 1.0. Offsetting the larger indexes are some that are as small as .2. The averages are about .4 for the subgroups studied.

Some general comments that can be made about the results shown in table G are:

1. The indexes of inconsistency for the category "\$10,000 or more" are generally smaller for most of the populations studied. They are about .2, in contrast to the larger ones of .4 and .5 that are common to the other categories. To some extent, the indexes are functions of the width of the class interval. All categories are intervals of \$500, except the "\$10,000 or more" category, which is much wider.

2. There is little variation among geographic region in the sizes of the indexes of inconsistency. For the categories for which larger indexes are produced, it is the pattern over all regions. A similar pattern holds for those categories for which small indexes are produced.

Table G. Indexes of Inconsistency and Their Standard Errors for Total Personal Income, by Population Subgroup

Total personal income	United States	Geographic region					Racial group, by level of education						
		North-east	North Central	South	West	Total white	White, 25 years and over			Total Negro and other races	Negro and other races, 25 years and over

NA Not available. Indexes are not computed for categories which comprise 1 percent or less of the population under study or for groups for which the total sample size is less than 100. For cases for which the estimated standard error is shown as .00, the reader is reminded that the standard error is undoubtedly positive.

¹No estimate of the standard error is provided when the sample size is small and the index is large.

Note: For cases for which the estimated standard error is shown as .000, the reader is reminded that the standard error is undoubtedly positive.

3. Indexes of inconsistency are generally larger for Negroes and other races than for the white population for the lower income categories. Thus, up to \$3,500 there is only one time when the index is larger for the white population. In that one case, the difference is so small it could be due to sampling error.

4. Within the white population, there is not much variability in the sizes of the index for the three educational attainment groups. Among Negroes and other races, the sampling errors are so large that it is difficult to make any statements about the relative sizes of the indexes for the three educational attainment groups.

5. There are no important differences among the indexes for the different age groups or for the levels of education.

Table H shows the estimates of bias for the populations studied. Most of the estimates are small, with a few exceptions. Some comments on the results shown in table H are as follows:

1. The largest bias was for the category "no income" for which the census overestimated the number of people. During the reinterview, people were asked specifically about small amounts that they might not tend to remember. Thus, for many of the populations studied, we see negative biases for the category "\$1 to \$499 or loss," indicating that there was an understatement of the number of people

in this category. This agrees with the results of other studies, but the reinterview seriously understates the level of this bias.

2. There seems to be very little difference among the four geographic regions in the estimates of bias. Most of the estimates for the regions are small.

3. Except for the no income category, there was little difference in the estimates of bias for the white population and Negroes and other races.

4. Within the white population, most of the bias estimates were small. For the categories which were somewhat larger, the estimates were of the same magnitude for all three educational attainment groups. Because of the size of the sampling error for the three educational attainment groups for Negroes and other races, we can say nothing about the relative magnitudes of these biases.

5. Since most of the estimates were small, they were small for all three age groups. There were some differences for the no income category for which the estimate of bias was somewhat larger for the 25 to 44 year age group. However, the sampling error for the 14 to 24 year age group was quite large and so the bias could be as large as that for the 25 to 44 year age group.

6. Any differences that may exist within the age groups by educational attainment are obscured by the size of the sampling errors.
